

# Delegation

|                    |  |  |                              |
|--------------------|--|--|------------------------------|
| Origin:            | Grand 98   |  |                              |
| Reason:            | An object needs to be different subclasses at different times.   |  |                              |
| Synopsis:          | Extend a class <i>C</i> by writing an additional class <i>D</i> with added functionality that uses instances of <i>C</i> .   |  |                              |
| Example:           | An airline reservation system has roles such as <i>flight crew</i> , <i>passenger</i> , <i>ticket agent</i> , etc. A <i>person</i> can play different roles at different times, and more than one role at a time. Inheritance makes this impossible. |  |                              |
| UML Class Diagram: | <pre> classDiagram     class Delegator     class Delegate     Delegator "1" -- "1" Delegate : Uses     </pre>  |  |                              |
| Solution:          | <b>Delegator</b>   | Uses <i>Delegate</i> .                             | Flight crew, Passenger, etc. |
|                    | <b>Delegate</b>  | Specializes <i>DelegateIF</i> to a specific role.  | Person                       |
|                    | <b>DelegatorIF</b>   | Base class or interface of all <i>Delegators</i> . | Role                         |
| Note:              | The example has two layers of delegation: <i>Role</i> to <i>Person</i> and <i>PersonWithRole</i> to <i>Role</i> .  |  |                              |
| Java API Usage:    | It is the basis for Java's delegation event model.   |  |                              |
| See also:          | <a href="#">Bridge</a> , <a href="#">Decorator</a> , <a href="#">Facade</a> , <a href="#">Proxy</a>  |  |                              |

# Interface

|                    |  |  |                      |
|--------------------|--|--|----------------------|
| Origin:            | Grand 98   |  |                      |
| Reason:            | A class needs to be independent of services provided by another class.   |  |                      |
| Synopsis:          | Abstract a class <i>C</i> by writing an interface <i>IF</i> . Clients access class <i>C</i> through interface <i>IF</i> .  |  |                      |
| Example:           | A business application uses an <i>Address</i> class in a variety of objects, e.g., <i>Vendors</i> , <i>Clients</i> , <i>Freight companies</i> , etc. To make these objects less dependent of the details of the <i>Address</i> class, the objects should rather use an interface, <i>AddressIF</i> . |  |                      |
| UML Class Diagram: | <pre> classDiagram     class Client     class IndirectionIF {         &lt;&lt;interface&gt;&gt;     }     class Service     Client "1" -- "1" IndirectionIF : uses     IndirectionIF &lt; .. Service : implements     </pre>   |  |                      |
| Solution:          | <b>Service</b>   | A class that provides data and/or methods to the <i>Client</i> . | Address              |
|                    | <b>Client</b>  | A class that uses the services of class <i>Service</i> .         | Vendor, Client, etc. |
|                    | <b>ServiceIF</b>   | Interface of class <i>Service</i> .                              | AddressIF            |
| Java API Usage:    | Ex: <i>Java.io.FilenameFilter</i> is an interface to tell if a named file is included a collection.  |  |                      |
